IMPORTANT

Although these specifications have been carefully constructed, reviewed, and used as the basis of implementation, some errors, oversights, and ambiguities are inevitable. The first author will post errata, clarifications, and links to updated versions of this document at http://jeff.over.bz/papers.

Introduction

This technical report contains detailed specifications of several automated refactorings for Fortran, BC, and PHP. The specifications are written somewhat like an ANSI or ISO programming language specification, mathematically informal but precise, in English prose but with sufficient detail to serve as a basis for implementation.

To the extent possible, the constructs in each language are described syntactically. For example, an External Subprogram in Fortran is defined to be a \(\language \) function-subprogram \(\) or a \(\language \) subprogram \(\) nested under an \(\language \) external-subprogram \(\rangle \). Such \(\langle \) bracketed-names \(\rangle \) correspond to nonterminal symbols in a normative grammar for each programming language: the grammar in the ISO standard for Fortran 95 [1], the grammar in the POSIX specification for BC [2], and the Yacc grammar in the source code for the official distribution of PHP 5 [3]. The BC and PHP grammars use recursive productions to form lists of elements; in these cases, we will often ignore the recursive structure and, instead, refer to the list as a whole (e.g., "remove X and an appropriate adjacent comma from the list"), since implementations are likely to represent them as a list structure rather than a tree in abstract syntax anyway.

All algorithms are described imperatively, as a sequence of steps that may be executed to test the precondition or perform the transformation. It is not essential that an implementation execute these steps in the order listed; in many cases, the steps can be reordered and still produce the same results. For example, many precondition checks require a number of conditions to be checked, but these conditions are mutually disjoint, and therefore the order in which they are checked is inconsequential.

Terminology

This document contains four types of descriptions. **Predicates** return either TRUE or FALSE and are used in the specification of preconditions. **Preconditions** either PASS or FAIL and are used in the specification of refactorings. **Refactorings** consist of a list of preconditions and a program transformation. All of the preconditions must PASS if the program transformation is to be applied. **Procedures** describe algorithms used in the definition of a predicate, precondition, refactoring, or another procedure. Generally they will return a value.

The following conventions are used throughout.

in the immediate context of. A syntactic construct occurs in the immediate context of another if the former is an (immediate) child of the latter in a parse tree. For example, the Fortran 95 grammar contains the production ⟨program-stmt⟩ ::= PROGRAM ⟨program-name⟩;

so if a program contained the statement program hello, then hello would be a $\langle program-name \rangle$ which occurred in the immediate context of a $\langle program-stmt \rangle$.

- **in the context of.** A syntactic construct occurs *in the context of* another if the former is a descendent of the latter in a parse tree. It may be a child, grandchild, great-grandchild, etc.
- **contains.** A syntactic construct *contains* another syntactic construct if the former is an ancestor of the latter in a parse tree. (Note that A contains B if, and only if, B occurs in the context of A—i.e., these terms are opposites.)
- **existing vs. new.** When it is not clear from context, syntactic constructs will be qualified as either an *existing* (i.e., the construct exists in the program being analyzed/transformed) or *new* (i.e., the construct is constructed from

scratch or supplied by the user). For example, the Rename refactoring takes two names as input: an existing name—this is the entity in the program that will be renamed—as well as a new name for that entity.

← When a refactoring must construct new syntax to be inserted into a program, the new construct is given in the concrete syntax of the language. Consider the following example.

```
given a \langle subroutine-name \rangle N, append to the \langle program \rangle \langle subroutine-subprogram \rangle \leftarrow subroutine N \triangleleft end subroutine \triangleleft
```

(The symbol \triangleleft indicates an end-of-line.) This means, "Construct a new $\langle subroutine\text{-}subprogram \rangle$ corresponding to the given concrete syntax (with the new subroutine name substituted for N), and append it to the $\langle program \rangle$." (The meaning of "the $\langle program \rangle$ " would presumably be clear from context.) The left arrow is intended to denote that the new construct may be parsed from the given concrete syntax (although implementations may choose to construct the equivalent abstract syntax programmatically).

- ♦ In refactoring specifications, steps in which source code may be modified have been labeled with a black diamond.
- In some refactorings specifications, the precondition checks and the transformation traverse the program in similar ways. In these cases, it was simpler to intermix precondition checking steps with transformation steps. Precondition steps have been labeled with a white diamond.

Organization

The remainder of this technical report is organized as follows. One part is devoted to each language: Fortran, BC, and PHP. Each part begins with a list of definitions specific to that language. Defined terms are subsequently capitalized in order to make their usage more apparent. Following the list of definitions is a list of *requirements*—expectations that are made about the semantic analysis capabilities of the refactoring tool. For the most part, these are roughly equivalent to the capabilities of a (partial) compiler front end coupled with a cross-reference database.

The list of requirements is followed by a set of common predicates, preconditions, and procedures. These have been "factored out" of the refactoring specifications in order to keep the latter more concise and to avoid redundancy. These have each been given a two-letter abbreviation, enclosed in square brackets. Predicates and preconditions are abbreviated using two capital letters, e.g., [SI] or [LC]. Procedures are appreviated with a capital and lowercase letter, e.g., [Pr]. These abbreviations are used subsequently to indicate explicitly that a particular predicate, precondition, or procedure is being referenced.

Each part concludes with specifications of refactorings. Again, capitalization and abbreviations are used to indicate references to defined terms, predicates, preconditions, and procedures.

Differential Refactoring

The specifications in this technical report are used to support "Differential Precondition Checking," a paper submitted for publication. The *Notes* under certain preconditions and refactorings relate to that material. In that paper, the evaluation is based on counting the number of *steps* each refactoring comprises. Each numbered item in a predicate, procedure, precondition, or refactoring counts as a single step. The total number of precondition checking steps for a refactoring is the sum of the steps for all predicates, preconditions, and procedures required to implement that refactoring's precondition checks. The following tables indicate the number of steps in each predicate, precondition, procedure, and refactoring. The *Trad*. line indicates the number of steps in the traditional specification, while the *Diff*. line indicates which precondition checking steps were eliminated by use of a differential precondition checker.

Part I Fortran

1 Definitions

Body. The statements between the header statement and the end-statement of a construct. E.g., for a $\langle module \rangle$, the Body consists of the statements between the $\langle module\text{-}stmt \rangle$ and $\langle end\text{-}module\text{-}stmt \rangle$.

Declaration. An occurrence of a name that first introduces it into a Lexical Scope. Syntactically, one of the following:

- 1. \(\langle type-name \rangle\) in the immediate context of a \(\langle derived-type-stmt \rangle\)
- 2. $\langle component-name \rangle$ in the immediate context of a $\langle component-decl \rangle$
- 3. *(object-name)* in the immediate context of an *(entity-decl)*
- 4. \(\langle namelist-group-name \rangle \) in the immediate context of a \(\langle namelist-stmt \rangle \)
- 5. \(\langle common-block-name \rangle \) in the immediate context of a \(\langle common-stmt \rangle \)
- 6. \(\langle \text{where-construct-name} \rangle \) in the immediate context of a \(\langle \text{where-construct-stmt} \rangle \)
- 7. \(\langle forall-construct-name \rangle \) in the immediate context of a \(\langle forall-construct-stmt \rangle \)
- 8. \(\langle if-construct-name \rangle\) in the immediate context of a \(\langle if-then-stmt \rangle\)
- 9. \(\langle case-construct-name \rangle \) in the immediate context of a \(\langle select-case-stmt \rangle \)
- 10. \(\langle do-construct-name \rangle\) in the immediate context of a \(\langle label-do-stmt \rangle\) or \(\langle nonlabel-do-stmt \rangle\)
- 11. \(\rhoprogram-name\)\) in the immediate context of a \(\rhoprogram-stmt\)\)
- 12. \(\langle module-name \rangle\) in the immediate context of a \(\langle module-stmt \rangle\)
- 13. $\langle local\text{-}name \rangle$ in the immediate context of a $\langle rename \rangle$ or $\langle only\text{-}rename \rangle$
- 14. \(\langle block-data-name \rangle\) in the immediate context of a \(\langle block-data-stmt \rangle\)
- 15. $\langle generic\text{-}name \rangle$, $\langle defined\text{-}operator \rangle$, or = in the immediate context of an $\langle interface\text{-}stmt \rangle$
- 16. \(\langle external-name \rangle \) in the immediate context of an \(\langle external-stmt \rangle \)
- 17. (*intrinsic-procedure-name*) in the immediate context of an (*intrinsic-stmt*)
- 18. \(\langle function-name \rangle \) in the immediate context of a \(\langle function-stmt \rangle \)
- 19. (*subroutine-name*) in the immediate context of a (*subroutine-stmt*)
- 20. \(\langle entry-name \rangle \) in the immediate context of an \(\langle entry-stmt \rangle \)
- 21. \(\langle function-name \rangle \) in the immediate context of a \(\langle stmt-function-stmt \rangle \)
- 22. The first occurrence of a variable name which causes that variable to become implicitly declared.

Definition. A Declaration that is *not* any of the following:

- 1. \(\langle external-name \rangle \) in the immediate context of an \(\langle external-stmt \rangle \)
- 2. \(\langle intrinsic-procedure-name \rangle \) in the immediate context of an \(\langle intrinsic-stmt \rangle \)
- 3. \(\langle function-name \rangle \) or \(\langle subroutine-name \rangle \) in the immediate context of a \(\langle function-stmt \rangle \) or \(\langle subroutine-stmt \rangle \) in the immediate context of an \(\langle interface-body \rangle \)

Except for common blocks, every entity is assumed to have at most one Definition (assuming the Fortran program is valid).†

External Subprogram. A subprogram defined in File Scope; i.e., a \(\langle function-subprogram \rangle \) or \(\langle subroutine-subprogram \rangle \) in the immediate context of an \(\langle external-subprogram \rangle \). (See File Scope.)

File Scope. A \(\rangle program \rangle\). (A File Scope is one kind of Lexical Scope; see Lexical Scope.\(\frac{\dagger}{\dagger}\)

Global Entity. A Program Unit or a *(common-block)*. (§14.1.1) (Note that a Global Entity may have multiple Declarations: An External Subprogram may also be declared in INTERFACE blocks and/or EXTERNAL statements, and a common block will usually be declared in several different common statements in other scopes.)

Host. A program unit that may contain a contains statement and internal subprograms or module subprograms. Syntactically, one of \(\lambda main-program \rangle \), \(\lambda module \rangle \), \(\lambda function-subprogram \rangle \) or \(\lambda subroutine-subprogram \rangle \) in the immediate context of an

(internal-subprogram) cannot be a Host. [4, pp. 448, 544]

Import. If a Named Entity in a Scoping Unit S is use associated (§11.3.2) with a Named Entity N from a module M, we will say S *Imports* N from M.

Internal Subprogram. A subprogram following a contains statement in a Host, i.e., a (*function-subprogram*) or (*subroutine-subprogram*) in the immediate context of an (*internal-subprogram*). [4, pp. 534–537]

Lexical Scope. A \(\rangle program \rangle \) or a Scoping Unit.\(\dagger^{\pm}\)

Local Entity (Class 1, 2, 3). Cf. §14.1.2. Refactorings herein deal exclusively with Class 1 Local Entities, which are "named variables that are not statement or construct entities (14.1.3), named constants, named constructs, statement functions, internal procedures, module procedures, dummy procedures, intrinsic procedures, generic identifiers, derived types, and namelist group names."

Local Scope. A Scoping Unit. (§14.1.2) [4, p. 534]

Name. A $\langle name \rangle$, or any syntactic construct named $\langle xyz\text{-}name \rangle$ (e.g., $\langle module\text{-}name \rangle$).

Named Entity. A Name, the assignment symbol "=", or a \(defined-operator \). (\§14) [4, p. 532]

Outer Scope. A Lexical Scope that properly contains a given Lexical Scope in a parse tree; i.e., a Lexical Scope which is an ancestor of a given Lexical Scope).

Program Unit. One of: \(\(\text{main-program} \) \), External Subprogram, \(\text{module} \) \), or \(\text{block-data} \). (\(\xi 11; R202 \))

Reference. Any occurrence of a Name that is not a Definition.

Scoping Unit. One of: \(\derived-type-def \), \(\main-program \), \(\delta odule \), \(\delta block-data \), \(\lambda function-subprogram \), \(\subseteq subroutine-subprogram \). [4, p. 532]

Subprogram. One of: \(\(\text{function-subprogram} \) \) or \(\text{subroutine-subprogram} \).

Subprogram Part. (The part of a Host that contains Internal Subprograms.) \(\(\text{module-subprogram-part} \) \(\text{or } \) \(\text{internal-subprogram-part} \).

Subroutine. A (*subroutine-subprogram*).

[†] Some entities may be declared in several locations. For example, an external subroutine may be defined in one file, while an interface block makes it available in another scope. In such cases, the declaration in the interface block is both a Declaration and a Reference, but it is *not* a Definition.

[‡] Our concept of a Lexical Scope is different from the concept of "scope" in the Fortran standard [4, pp. 534–537]. Specifically, implied-DO variables, FORALL index variables, and statement-function parameters exist in a new scope according to the ISO specification, but for our (refactoring) purposes, we will treat them as references to a local variable in the enclosing scope. Also, the concept of File Scope is new.

2 Requirements

We will assume that the refactoring tool's capabilities are roughly those of a parser coupled with a syntax tree rewriter, name binding analysis (symbol tables), and cross-reference database. This means that the tool is able to construct and traverse a syntax tree, manipulate source code based on that syntax tree, find all Declarations of a Global Entity, find all Declarations in a given Lexical Scope (including implicit variables), find all References to a given Declaration, determine what type of entity a given name refers to (common block, local variable, function, etc.), determine an entity's attributes (PARAMETER, PUBLIC, etc.), find all Lexical Scopes which USE a particular module, and determine what entities are imported from that module.

3 Predicates, Preconditions, & Procedures

3.1 Predicate [LC]: Introducing N into S introduces a local conflict with N'

```
subroutine s
integer :: n
common /c/ n
contains
!! subroutine n cannot be introduced here
!! subroutine c can be introduced here
end subroutine
```

This determines whether two declarations cannot simultaneously exist in the same Lexical Scope.

Input. A new Named Entity N and an existing Named Entity N' with a Declaration in a Lexical Scope S, N and N' have the same name.

Procedure. 1. If N and N' both name Global Entities, return TRUE. (§14.1.1)

- 2. If N is the name of a common block and N' names a Local Entity, or vice versa, return FALSE. (§14.1.2)
- 3. If N is the name of an external procedure and N' is a generic name given to that procedure, return FALSE. (§14.1.2)
- 4. Otherwise, return TRUE. (§14.1.2)

Notes. This is a compilability check. A compiler uses these same rules when determining if a symbol can be added to the symbol table for a particular scope. If this predicate returns TRUE but N is introduced into S anyway, the program will not compile.

3.2 Predicate [SH]: Named Entity N in S cannot be shadowed in S'

```
subroutine s
integer :: n
contains
!! subroutine :: s cannot be introduced here
subroutine t
!! integer :: n can be introduced here
!! integer :: s can be introduced here
!! integer :: t cannot be introduced here
end subroutine
end subroutine
```

If there is a Named Entity N defined in S, this check determines if another entity in a contained Lexical Scope S' cannot also be named N.

Input. A Named Entity N defined in a Lexical Scope S, and a Lexical Scope S' contained in S.

Procedure.

- 1. If *S* is the File Scope, return FALSE. (Entities defined at File Scope are Global Entities. They are accessible to, but not inherited by, contained scopes.)
- 2. If S' is a Scoping Unit and N is the name of S', return TRUE. (The name of a main program, module, or subprogram has limited use within its definition. §11.1, 11.3, 14.1.2)
- 3. If S' is an Internal Subprogram, return FALSE. (Declarations in Internal Subprograms may shadow Declarations in their Hosts. §14.6.1.3)
- 4. Otherwise, return TRUE.

Notes.

This is a compilability check. A compiler uses these same rules when determining if a symbol can be added to the symbol table. If this predicate returns TRUE but N is introduced into S' anyway, the program will not compile.

3.3 Predicate [IC]: Introducing N into S introduces conflicts into an importing scope S'

 module m1
 module m2
 subroutine s

 integer :: a
 !! integer :: a cannot be introduced here integer :: b can be introduced here
 use m1; use m2

 integer :: b
 !! integer :: b can be introduced here end module
 print *, a

Suppose a new Named Entity N is to be introduced into a module, and another scope S' imports that module and will import N if it is introduced. This check determines whether S' already contains an entity with the same name as N.

Input. A new Named Entity N, a module S, and a Lexical Scope S' that (directly or indirectly) imports entities from the module S.

Procedure. 1. If there is an entity N' in scope in S' with the same name as N...

- (a) If N' is imported from a module but is unreferenced[†] in S', return FALSE. (§11.3.2) (This includes both the case where N' is imported without renaming and the case where N' is a $\langle local-name \rangle$ for a renamed module entity.)
- (b) If N' is inherited in S' from an Outer Scope, return TRUE iff N' cannot be shadowed by N in S [SH].
- (c) Otherwise, return TRUE iff introducing N introduces a local conflict [LC] with N'.
- 2. Otherwise, return FALSE.[‡]

Notes. This is a compilability check. If this predicate returns TRUE but N is introduced into S anyway, the program will not compile.

[†] There is some ambiguity as to what "unreferenced" means. The relevant clause of the ISO standard (§11.3.2) states: "Two or more accessible entities, other than generic interfaces, may have the same name only if the name is not used to refer to an entity in the scoping unit." The question is what "refer to" means. Specifically, (1) is USE M, $X \Rightarrow A$, $X \Rightarrow B$ legal if the name X is never actually used, and (2) if M contains a module entity named X, should USE M, $X \Rightarrow A$ be permitted (in which case the local name X would presumably shadow the module entity X? IBM XL Fortran 12.1, GNU Fortran 4.4.2, PGI Fortran 10.0, and Intel Fortran 10.1 all exhibit different behaviors.

 ‡ There may be an entity with the same name in a contained scope, but it will be allowed to shadow the imported entity N; cf. [SH].

3.4 Predicate [SK]: Introducing N into S skews references in S'

```
module m
integer n
contains
subroutine s
!! integer :: n cannot be introduced here
call t
contains
subroutine t
n = 1
end subroutine
end subroutine
end module
```

In the above code, a local variable named n cannot be introduced into s because it would change the meaning of the reference to n in t, which could change the behavior of a program. This predicate detects situations such as this.

Suppose a new Named Entity N is to be introduced into a scope but shadows an existing entity N'. This check determines whether any references to N' will instead become references to N if it is introduced.

Input. A new Named Entity N, a Lexical Scope S into which N is intended to be introduced, and a Lexical Scope S' which is either S itself or a Lexical Scope contained in S.

Procedure. 1. For each reference in S' to a Named Entity N' with the same name as N...

- (a) If N' is inherited from a scope S'' (where S' is contained in S''), return TRUE. (§14.6.1.3) (If N is introduced into S', N will shadow N', changing the reference.)
- (b) If N' is a reference to a procedure whose name has not been established (§14.1.2.4.3), return TRUE. (If N is introduced into S', the name will be established, changing the reference.)
- 2. For each Lexical Scope S" contained in S', return TRUE if introducing N into S skews references [SK] in S".
- 3. Otherwise, return FALSE.

Notes.

This is both a compilability and a semantic preservation check. If bindings are skewed, say, from a variable to a subroutine, the program will not compile; if they are skewed, e.g., from one variable to another, behavior might not be preserved. In any case, if this predicate returns TRUE, name bindings will not be preserved if the transformation proceeds.

3.5 Precondition [IN]: Introducing N into S must be legal and name binding-preserving

This precondition makes two guarantees: (1) if a particular declaration is added to a program, the resulting program will compile (i.e., the addition of the declaration is legal); and (2) if the declaration will shadow another declaration, it will not inadvertently change references to the shadowed declaration.

Input. A new Named Entity N and a Lexical Scope S.

Procedure.

- 1. If there is a Named Entity N' in scope in S which has the same name as $N \dots$
 - (a) If N' is local to S or is imported into S, FAIL if introducing N introduces a local conflict [LC] with N' in S.
 - (b) If N' is declared in an Outer Scope, FAIL if N' cannot be shadowed [SH] by N in S.
 - (c) Fail if the introduction of N in S skews references [SK] in S.
- 2. For each Lexical Scope S' contained in S, if there is a Named Entity N' with the same name as N that is local to S' or is imported into S', FAIL if N cannot shadow [SH] N' in S'.
- 3. For each Lexical Scope S' that imports S, if S' will import N due to the absence of an only clause...
 - (a) Fail if the introduction of N in S introduces conflicts [IC] into the importing scope S'.
 - (b) Fail if the introduction of N in S' skews references [SK] in S'.
- 4. Pass.

Notes.

This precondition combines the previous four predicates into a single check which guarantees that, if N is introduced into S, then (1) the program will compile, and (2) name bindings will be preserved. The previous four predicates enumerate all of the conditions required for this guarantee to be made *a priori*. In a differential refactoring engine, this precondition can be eliminated entirely, since introducing N into S and testing for compilability and name binding preservation satisfies this precondition's checks: If name bindings will be skewed, predicate [SK] will fail. If the resulting program will not compile, one of predicates [LC], [SH], or [IC] will fail.

3.6 Precondition [SI]: Non-generic Internal Subprogram S must have only internal references

This precondition guarantees that there are no calls to a given Internal Subprogram except for directly recursive calls.

Input. An Internal Subprogram S in a Host H. S must not be a generic subprogram.

Procedure. 1. For each Reference *R* to *S*, FAIL if *neither* of the following hold:

- (a) R occurs in the context of an $\langle access-stmt \rangle$ in the $\langle specification-part \rangle$ of H.
- (b) R occurs in the Definition of S.
- 2. Pass.

3.7 Predicate [PR]: Private Entities in D are referenced outside D

Given a set D of module entities, this predicate determines whether any entities in D with private visibilities are referenced by definitions that are not in D.

Input. A set *D* of Named Entity Definitions in a Module *M*.

Procedure. 1. For each Named Entity N in D...

- (a) If N has private visibility, then...
 - i. For each Reference R to N...
 - A. If *R* does not occur in the Definition of an entity in *D*, return TRUE.
- 2. Return false.

Notes. See Precondition [PP] and the refactoring Move Module Entities.

3.8 Procedure [Ou]: Determine Named Entities in M-D referenced by D

Given a set D of module entities, this predicate determines whether any definitions in D reference entities in the module that are not included in D.

Input. A set *D* of Named Entity Definitions in a Module *M*.

Output. A set E of Named Entities in a Module M.

Procedure. 1. Initially, let $E := \emptyset$.

- 2. For each Named Entity *N* in *D*...
 - (a) For each Reference R in the Definition of N...
 - i. If *R* names a public module entity from *M* that is not in the set *D*, define $E := E \cup \{N\}$.
- 3. Return E.

3.9 Predicate [OU]: D references Named Entities in M outside D

Given a set D of module entities, this predicate determines whether any definitions in D reference entities in the module that are not included in D.

Input. A set D of Named Entity Definitions in a Module M.

Procedure. 1. Determine the set E of Named Entities in M-D referenced by D [Ou].

2. Return true iff $E \neq \emptyset$.

Notes. See Precondition [PP] and the refactoring Move Module Entities.

3.10 Precondition [PP]: D must partition private references in M

Given a set D of module entities, this precondition ensures that references to PRIVATE entities occur such that either (1) both the entity and the reference are in D, or (2) neither the entity nor the reference is in D.

Input. A set D of Named Entity Definitions in a Module M.

Procedure. Let \overline{D} denote the set of all module entities declared in M that are not members of the set D.

- 1. Fail if private entities in D are referenced outside D [PR].
- 2. Fail if private entities in \overline{D} are referenced outside \overline{D} [PR].
- 3. Pass.

3.11 Procedure [Pr]: Construct a Set of Pairs from Use Statement U

Given a USE statement, this procedure returns a set of ordered pairs which model the module entities imported by that USE statement. The first component of each pair is the name of the module entity; the second component is its name in the local scope, which may be the same or different from the original name. For example, suppose a module MOD contains entities named a, b, and c. For the statement USE MOD, this procedure would return $\{(a,a),(b,b),(c,c)\}$; for the statement USE MOD, x > c, it would return $\{(a,a),(b,b),(c,x)\}$; and for the statement USE MOD, ONLY: a, x > b, it would return $\{(a,a),(b,x)\}$.

Input. A $\langle use\text{-}stmt \rangle U$.

Output. A set of ordered pairs of Names.

Procedure. Let N_M denote the set of names of all public entities in the module referenced by U.

1. If U contains neither a $\langle rename-list \rangle$ nor an $\langle only-list \rangle$, return

$$\bigcup_{N\in N_M}(N,N).$$

2. If *U* contains a $\langle rename-list \rangle$, return

$$\bigcup_{N \in N_M} \begin{cases} \{(N, N')\} & \text{if } N' => N \text{ appears in the } \langle \textit{rename-list} \rangle, \text{ for some } N' \\ \{(N, N)\} & \text{if } N \text{ does not appear as a } \langle \textit{use-name} \rangle \text{ in the } \langle \textit{rename-list} \rangle \end{cases}$$

3. If U contains an $\langle only-list \rangle$, return

$$\bigcup_{N \in N_M} \begin{cases} \{(N,N')\} & \text{if } N' => N \text{ appears in the } \langle only\text{-}list \rangle, \text{ for some } N' \\ \{(N,N)\} & \text{if } N \text{ appears in the } \langle only\text{-}list \rangle \\ \varnothing & \text{if } N \text{ does not appear in the } \langle only\text{-}list \rangle \end{cases}$$

3.12 Procedure [Us]: Construct a Use Statement for Module M from Sets of Pairs X and Y

This procedure is essentially the opposite of Procedure [Pr]: It takes as input a set of ordered pairs and uses them to construct a USE statement. For example, for the module name mod and ordered pairs $\{(a,a),(b,x)\}$, it would return the statement USE MOD, ONLY: a, x > b.

Input. 1. A Name *M* of a module.

2. A set *X* of ordered pairs of Names. (This set denotes the entities that the USE statement should import.)

3. A set *Y* of ordered pairs of Names of entities with public visibility in *M*. (This set denotes *all* of the public entities available to import from *M*. This set is provided as input to accommodate the Move Module Entities refactoring: it will need to construct a USE statement assuming that some entities have been moved out of one module and into another.)

Output. A new $\langle use\text{-}stmt \rangle U$.

- **Procedure.** 1. If $\{N \mid \exists N' . (N, N') \in X\} = \{L \mid \exists L' . (L, L') \in Y\}$, then every entity in *M* is imported.
 - (a) If X = Y, then every entity in M is imported, and no entites are renamed, so return

$$\langle use\text{-}stmt \rangle \leftarrow use M \neq$$

(b) If $\{N \mid \exists N' \neq N. (N, N') \in X\} \neq \emptyset$, then every entity in M is imported, but at least one entity is renamed. Let $(N_1, N_1'), (N_2, N_2'), \dots, (N_k, N_k')$ denote the members of the set $\{(N, N') \in X \mid N \neq N'\}$, and return

$$\langle \textit{use-stmt} \rangle \leftarrow \text{use } M, N_1' \Rightarrow N_1, N_2' \Rightarrow N_2, \dots, N_k' \Rightarrow N_k \notin \mathcal{N}_{k+1}$$

- 2. Otherwise, not all members of *M* are imported.
 - (a) Initally, let U denote the $\langle use\text{-}stmt \rangle$

$$\langle \mathit{use}\text{-}\mathit{stmt} \rangle \leftarrow \mathit{use} \ \mathit{M}$$
, only: \triangleleft

which has an empty $\langle only-list \rangle$.

- (b) For each pair (N, N') in X...
 - i. If N = N', append

$$\langle only\text{-}use\text{-}name \rangle \leftarrow N$$

to the $\langle only\text{-}list \rangle$ of U (with a separating comma, if necessary).

ii. If $N \neq N'$, append

$$\langle only\text{-}rename \rangle \leftarrow N' \Rightarrow N$$

to the $\langle only-list \rangle$ of U (with a separating comma, if necessary).

(c) Return U.

3.13 Precondition [RN]: Module M' must not rename entities D from Module M

Given a set D of entities defined in a module M, this precondition ensures that, if any entities in D are directly imported into M', they are not renamed.

Input. A set D of Named Entity Definitions in a Module M.

Procedure. 1. If M' contains a $\langle use\text{-}stmt \rangle U'$ with a $\langle module\text{-}name \rangle$ naming M...

- (a) Construct a set of pairs X from U' [Pr].
- (b) If X contains an element (N, N') where $N \in D$ and $N \neq N'$, FAIL.
- 2. Pass.

3.14 Procedure [Rn]: Replace References in C according to X

This procedure replaces occurrences of one name with a different name.

Input. 1. A set X of ordered pairs (N, N') where N is an existing Name and N' is a new Name.

2. Any syntactic construct C.

Output. C is modified such that References to N have their name changed to N'.

Procedure. 1. For each pair $(N, N') \in X...$

- (a) For each Reference R to N in C...
 - i. Replace the occurrence of N in R with N'.

4 Refactorings

4.1 Add Empty Internal Subroutine

This refactoring adds a new Subroutine as an Internal Subprogram of a given Host. The Subroutine initially has an empty body. The refactoring fails if the Subroutine will conflict with an existing declaration. Although this refactoring may be used by itself, but it is perhaps more useful as a building block for other refactorings (like Extract Subroutine).

- **Input.** 1. A Host *H* into which the empty subroutine will be added as an internal subprogram.
 - 2. A new Name *N* for the subroutine.

Preconditions. Introducing an Internal Subprogram into H with name N must be legal and name binding-preserving [IN].

Transformation. 1. \blacklozenge If H does not contain a Subprogram Part, append to H

 $\begin{array}{ccc} \text{Subprogram Part} & \leftarrow & \text{contains } \rlap{\slash} \rlap{\slash} \\ & & \text{subroutine } N \not \rlap{\slash} \end{matrix}$ end subroutine $\rlap{\slash} \rlap{\slash}$

Requires: [LC],[SH],[IC],[SK],[IN]

Requires: [SI]

2. \blacklozenge If H contains a Subprogram Part P, append to P

 $\langle internal\text{-}subprogram \rangle \leftarrow \text{subroutine } N \triangleleft$ end subroutine \lozenge

Notes.

In a differential refactoring engine, precondition [IN] can be eliminated as described in its description. The new subroutine must not shadow an existing entity (i.e., skew references), which would be manifested as an incoming binding. It must not conflict with an existing entity, which would result in a compilation error. The addition of a new subroutine cannot introduce an outgoing name binding (although introducing a new function could, depending on its return type). Control flow and du-chains are intraprocedural and, therefore, are unaffected. The only new name binding edge will be an internal edge from the $\langle end-name \rangle$ to the $\langle subroutine-name \rangle$. Therefore, the differential version of this refactoring consists of a single step: introducing the subroutine with rule $N \subseteq$

4.2 Safe-Delete Non-Generic Internal Subprogram

This refactoring removes an Internal Subprogram from a given Host. The refactoring fails if there are any references to the subprogram.

Input. An Internal Subprogram *S* in a Host *H*.

Preconditions. S must have only internal references [SI].

Transformation. 1. For each Reference to S in an $\langle access-stmt \rangle$ A in the $\langle specification-part \rangle$ of H...

- (a) \blacklozenge If the $\langle access-id-list \rangle$ of A contains only one $\langle access-id \rangle$ (i.e., a $\langle use-name \rangle$ with the name of S), remove A.
- (b) \blacklozenge If there is more than one $\langle access-id \rangle$ in the $\langle access-id-list \rangle$ of A, remove the $\langle use-name \rangle$ with the name of S and an appropriate adjacent comma.
- 2. \blacklozenge If *H* contains only one Internal Subprogram (*S*), remove the Subprogram Part of *H*.
- 3. \blacklozenge If *H* contains more than one Internal Subprogram, remove *S*.

Notes. This specification requires that the subprogram not be used in an (*interface-block*). Extending the refactoring to remove this restriction is straightforward.

In a differential refactoring engine, the precondition [SI] can be eliminated. There must be no incoming bindings to the entity to delete; deleting a referenced subroutine would be manifested as a missing incoming binding. A subroutine may contain variable references and subroutine calls, so outgoing bindings may be deleted. Internal name binding edges, representing recursive calls and the link from the $\langle end-name \rangle$ to the $\langle subroutine-name \rangle$, will also be deleted. Control flow and du-chains are intraprocedural and, therefore, are unaffected. Therefore, this refactoring consists of a single step: deleting the subroutine according to rule $N \in \mathbb{C}$.

4.3 Rename Requires: [IN],[LC],[SH],[SK],[IC]

This refactoring changes the name of an entity, both in declarations and references. It fails if the new name will conflict with an existing name, or if it will shadow an existing name in such a way that existing name bindings will change.

Input. 1. A Declaration of a Name *N* in a Lexical Scope *S* . *N* must designate a Global Entity or Class 1 Local Entity.

2. A new Name N' for N.

Preconditions. 1. Introducing N' into S must be legal and name binding-preserving [IN].

- 2. Warn if a reference to *N* appears in the context of a *(namelist-group-object)*: To preserve behavior, the user may need to manually update input files to reflect the new variable name.
- 3. If *N* names a subprogram, matching declarations in INTERFACE blocks should uniquely bind to *N*.

Transformation. 1. For each Declaration D of the Named Entity N...

- (a) \blacklozenge Replace D with N'.
- (b) For each Reference R to D...
 - i. \blacklozenge Replace R with N'.

Notes. In a differential refactoring engine, precondition [IN] can be eliminated as described in its description. This refactoring should preserve the program graph in its entirety.

4.4 Introduce Implicit None

This refactoring adds an IMPLICIT NONE into a Lexical Scope and all nested scopes and adds type declaration statements for all implicit variables. Its specification is greatly simplified by the infrastructural assumptions stated in Section 2.

Input. A Lexical Scope S.

Preconditions. (none)

Transformation. 1. If IMPLICIT NONE does *not* appear in the $\langle specification-part \rangle$ of $S \dots$

Let I' denote

 $\langle implicit - stmt \rangle \leftarrow implicit none \langle$

Requires: none

- (a) \blacklozenge If an $\langle implicit\text{-}stmt \rangle I$ appears in the $\langle specification\text{-}part \rangle$ of S, replace I with I'.
- (b) ♦ If such an ⟨implicit-stmt⟩ does not appear, insert I' into the ⟨specification-part⟩ of S. (Note that the Fortran grammar requires that I' appear after all occurrences of ⟨use-stmt⟩ but before all occurrences of ⟨declaration-construct⟩.)

(c) For each implicitly-typed variable N which is local to $S \dots$

Let T be a new $\langle type\text{-}spec \rangle$ corresponding to the type of N. (If the $\langle implicit\text{-}stmt \rangle$ I existed in Step 1a above, it is preferable to copy the concrete syntax of the $\langle type\text{-}spec \rangle$ from the existing $\langle implicit\text{-}stmt \rangle$, when possible, in order to ensure that formatting and symbolic representations of kinds are reproduced verbatim.)

i. \blacklozenge Insert the following into the $\langle specification-part \rangle$ of S:

 $\langle declaration\text{-}construct \rangle \leftarrow T :: N \triangleleft$

2. Repeat Step 1 for each Lexical Scope S' contained in S.

Notes.

This refactoring has no preconditions, since it is always legal to add explicit type declaration statements. If a scope is already IMPLICIT NONE, the transformation has no effect.

In a differential refactoring engine, this transformation will change name bindings such that they point to the variable declaration rather than the first occurrence of the variable name (which implicitly declared the variable). Therefore, the affected forest must consist of both the first occurrence of the variable and the explicit declaration; then, the refactoring will introduce a new internal name binding edge (from the first use to the explicit declaration) but will otherwise preserve the program graph in its entirety. Therefore, this refactoring consists of a single step: introducing the explicit declaration according to rule N_{\supseteq}° .

4.5 Permute Subroutine Parameters

This refactoring permutes the arguments to a subroutine, adjusting any call sites accordingly. Note that, if the actual arguments at a call site include function invocations with side effects, reordering these function calls may not preserve behavior.

Input. 1. A $\langle subroutine\text{-}subprogram \rangle S$ with n dummy arguments, $n \geq 2$, and

2. A permutation $\sigma = \begin{pmatrix} 1 & 2 \\ j_1 & j_2 & \dots & j_n \end{pmatrix}$ providing a new order for the arguments of S.

Preconditions.

1. Alternate return specifiers must retain the same relative order. That is, if the $\langle dummy-arg-list \rangle$ in S's $\langle subroutine-stmt \rangle$ has * for the $\langle dummy-arg \rangle$ s at indices i_1, i_2, \ldots, i_k where $i_1 < i_2 < \cdots < i_k$, then $\sigma(i_1) < \sigma(i_2) < \cdots < \sigma(i_k)$.

Requires: none

- 2. The permutation must not place an optional argument before an alternate return.
- 3. Matching declarations in INTERFACE blocks should uniquely bind to S.
- 4. (Checked during transformation)

Transformation.

- 1. \blacklozenge Permute the $\langle dummy-arg \rangle$ s in the $\langle dummy-arg-list \rangle$ of S's $\langle subroutine-stmt \rangle$ according to σ .
- 2. For each $\langle call\text{-}stmt \rangle C$ which references $S \dots$

The $\langle actual$ -arg-spec-list \rangle of C contains $m \langle actual$ -arg-spec \rangle s, for some $m \leq n$.

- (a) Initially, let K := FALSE.
- (b) Initially, let L' be an empty $\langle actual\text{-}arg\text{-}spec\text{-}list \rangle$.
- (c) For $i := \sigma(1), \sigma(2), \dots, \sigma(n)$:

Let D denote the i-th dummy argument of S before its dummy arguments were permuted. If C contains an $\langle actual$ -arg-spec \rangle corresponding to D, denote it by A_i .

- i. If A_i is not defined, define K := TRUE. (An optional argument was omitted, so all subsequent arguments must have keywords.)
- ii. If A_i is defined...

Let A_i denote the $\langle actual$ -arg-spec \rangle .

- A. If A_i contains $\langle keyword \rangle =$, define K := TRUE.
- B. If K = FALSE or A_i contains $\langle keyword \rangle =$, append A_i (with a separating comma, if necessary) to L'.
- C. \diamond Fail if K = true and A_i is an alternate return argument. (Permuting call sites must not place an alternate return argument after an argument with $\langle keyword \rangle =$, since every subsequent actual argument must contain $\langle keyword \rangle =$, but alternate return arguments cannot be given keywords.)
- D. If K = TRUE and A_i does not contain $\langle keyword \rangle =$, let N denote the $\langle dummy-arg-name \rangle$ of the i-th $\langle dummy-arg \rangle$ in S's $\langle subroutine-stmt \rangle$ before it was permuted, and append

$$\langle actual\text{-}arg\text{-}spec \rangle \leftarrow N = A_i.$$

to L'.

- (d) \blacklozenge Replace C's $\langle actual\text{-}arg\text{-}spec\text{-}list \rangle$ with L'.
- 3. For each $\langle subroutine-stmt \rangle$ S' in the context of an $\langle interface-block \rangle$ such that S' matches S...
 - (a) \blacklozenge Permute the $\langle dummy-arg-list \rangle$ of S' according to σ .

Notes.

In a differential refactoring engine, none of this refactoring's preconditions can be eliminated, because they are all related to input validation rather than compilability or preservation checking.

4.6 Add Use of Named Entities E in Module M to Module M' [Prerequisite]

Requires: [IN],[LC],[IC],[SH],[SK]

This refactoring adds the statement use M, only: E to the module M', if a similar statement does not already exist. It fails if this will result in a naming conflict, the introduction of circular dependencies between modules, or if a statement USE M already exists but renames entities in E.

- **Input.** 1. A Module M.
 - 2. A set *E* of public Named Entities in *M*.
 - 3. A distinct Module M'. The statement use M will be inserted into M', if necessary.

Preconditions.

- 1. Fail if M uses M'. (It would be necessary to introduce the statement use M into M', but this would introduce a circular dependency.)
- 2. (Checked during transformation)

Transformation.

- 1. If M' contains a $\langle use\text{-}stmt \rangle U'$ with a $\langle module\text{-}name \rangle$ naming M, and U' contains an $\langle only\text{-}list \rangle \dots$
 - (a) For each Named Entity N in E that does not occur as a $\langle use\text{-}name \rangle$ in the context of U''s $\langle only\text{-}list \rangle$...
 - i. \diamond Ensure that introducing N into M' is legal and name binding-preserving [IN].
 - ii. ♦ Append a separating comma and

$$\langle onlv \rangle \leftarrow N$$

to the $\langle only-list \rangle$ of U'.

2. If M' does not contain a $\langle use\text{-}stmt \rangle$ with a $\langle module\text{-}name \rangle$ naming M...

Let E_1, E_2, \ldots, E_k denote the elements of E.

- (a) For each Named Entity E_i , $1 \le i \le k \dots$
 - i. \diamond Ensure that introducing E_i into M' is legal and name binding-preserving [IN].
- (b) ♦ Insert the statement

$$\langle use\text{-}stmt \rangle \leftarrow use M$$
, only: E_1 , E_2 , ..., $E_k \triangleleft$

into the $\langle specification-part \rangle$ of M'.

Notes.

This refactoring fails precondition checking if a USE statement already exists but renames an entity in *E*: This is to simplify Move Module Entities, for which this refactoring is a prerequisite. Instead, Move Module Entities could rename references according to the new local names.

The first precondition can be eliminated in a differential refactoring engine since introducing a circular dependency will result in a compilation error. The checks for precondition [IN] can also be eliminated as described in its description. Adding the use statements will introduce outgoing name bindings (to the imported entities), but the used names should be unreferenced; therefore, the use statements should be inserted according to rule $N \subseteq$.

4.7 Move Module Entities

Requires: [OU],[Ou],[LC],[RN],[PP],[PR],[Pr],[Us],[Rn]

This refactoring moves a set of entities from one module to another, updating USE statements as necessary. It fails if the changes will result in a naming conflict, a visibility problem, or the introduction of circular dependencies between modules.

Allowing the user to move a set of entities often simplifies the refactoring process since it allows a private module variable and all of the procedures that use it to be moved at once. If they are moved one at a time, it becomes necessary to temporarily increase the visibility of the module variables in the interim.

There are 21 different declaration constructs that can appear in a $\langle module \rangle$. To keep this specification to a resonable length, we require the entities to move to be referenced only in $\langle type$ -declaration-stmt \rangle s, $\langle access$ -stmt \rangle s, and procedure definitions (see Precondition 1a). Extending it to support other constructs should be straightforward.

- **Input.** 1. A set *D* of Named Entity Declarations in a Module *M*.
 - 2. A distinct Module M' into which the entities will be moved.

Preconditions.

- 1. For each Named Entity *N* in *D*...
 - (a) For each reference R to N which occurs in the context of M...
 - i. If R does not occur in the context of any of the following, FAIL:
 - \(\lambda\) type-declaration-stmt\(\rangle\)
 - \(\access\)-stmt\\
 - *(subroutine-subprogram)*
 - \(\langle function\)-subprogram\\
 - (b) For each Named Entity N' declared in M'...
 - i. Introducing N into M' must not introduce a local conflict [LC] with N'.
 - (c) Introducing N into M' must not skew references [SK] in M'.
- 2. M' must not rename entities D from M [RN].
- 3. D must partition private references in M [PP].

Transformation.

1. (If any of the entities being moved from M use other entities in M, add use M to M'.) If D references Named Entities in M outside D [OU]...

Let E denote the set of Named Entities in M outside D that are referenced by D.

- (a) \blacklozenge Add Use of Entities E in M to M' [Prerequisite].
- (b) Construct a Set U_E of Pairs from the Use Statement [Pr] created in the previous step. Let X denote the set $\{(N, N') \in U_E \mid N \neq N'\}$.

Let \overline{D} denote the set of all module entities declared in M that are not members of D.

2. (If any of the entities being moved from M are used by other entities in M that are not being moved, add use M to M.) If \overline{D} references Named Entities in M outside \overline{D} [OU]...

Let E denote the set of Named Entities in M outside \overline{D} that are referenced by D.

- (a) \blacklozenge Add Use of Entities E in M' to M [Prerequisite].
- 3. (If M' already contained a \(\)use-stmt \(\), remove any of the references to the entities that are being moved, since they will no longer be in M.) If M' contains a \(\)use-stmt \(\) U' with a \(\)module-name \(\) naming M...
 - (a) If U' contains an $\langle only-list \rangle$...
 - i. \blacklozenge If every $\langle only\text{-}use\text{-}name \rangle$ in the $\langle only\text{-}list \rangle$ is in D, remove the $\langle use\text{-}stmt \rangle$ U'.
 - ii. \blacklozenge Otherwise, remove from the $\langle only-list \rangle$ every $\langle only \rangle$ whose $\langle use-name \rangle$ is in D (also removing an appropriate adjacent comma).
- 4. (Update USE statements.) For each $\langle use\text{-stmt} \rangle U$ with a $\langle module\text{-name} \rangle$ naming M...

Let S denote the Lexical Scope containing the $\langle use\text{-}stmt \rangle$.

If S contains a $\langle use\text{-}stmt \rangle$ whose $\langle module\text{-}name \rangle$ names M', let U' denote this $\langle use\text{-}stmt \rangle$.

- (a) Construct a set U_M of pairs from U [Pr].
- (b) If U' does not exist, define $U_{M'} := \emptyset$; otherwise, Construct a set $U_{M'}$ of pairs from U' [Pr].

Let U_D denote the subset of U_M consisting of pairs whose first component names an entity in D. $U_D := \{(Q, Q') \mid Q \in D \land (Q, Q') \in U_M\}$.

Let P_M denote the set of pairs of public entities in M and P_D denote the subset of P_M consisting of pairs whose first component names an entity in D. $P_D := \{(C, C') \mid C \in D\}$.

- (c) Construct a Use Statement K for Module M with $X := U_M U_D$ and $Y := P_M P_D$ [Us].
- (d) Construct a Use Statement K' for Module M' where $X := U_{M'} \cup U_D$ and $Y := P_M \cup P_D$ [Us].
- (e) i. \blacklozenge If K does not have an empty $\langle only-list \rangle$, replace U with K.
 - ii. \blacklozenge If K has an empty $\langle only\text{-}list \rangle$, remove U.
- (f) i. \blacklozenge If U' exists, then remove U'.
 - ii. \blacklozenge If K' does not have an empty $\langle only\text{-}list \rangle$, insert K' into S.
- 5. (Move the declarations from M to M'.) For each Named Entity N in D...
 - (a) If N is a variable, and its Declaration is a $\langle type\text{-}declaration\text{-}stmt \rangle T...$
 - i. \blacklozenge If X is defined (from Step 1b), replace references in T according to X [Rn].
 - ii. \blacklozenge If T's $\langle entity\text{-}decl\text{-}list \rangle$ contains only one $\langle entity\text{-}decl \rangle$, (i.e., an $\langle entity\text{-}decl \rangle$ with the name of N), move T into the list of $\langle declaration\text{-}construct \rangle$ s in M'.
 - iii. If T's $\langle entity-decl-list \rangle$ contains more than one $\langle entity-decl \rangle$...

Let *E* denote the $\langle entity-decl \rangle$ with the name of *N* in *T*'s $\langle entity-decl-list \rangle$.

A. Create a copy T' of T.

- B. Replace T''s $\langle entity\text{-}decl\text{-}list \rangle$ with a list containing the single entry E.
- C. \blacklozenge Remove E and an appropriate adjacent comma from T.
- D. \blacklozenge Insert T' into the list of $\langle declaration\text{-}construct \rangle$ s in M'.
- (b) If *N* is a Subprogram whose Definition occurs in the context of a (*module-subprogram*) *S*...
 - i. \blacklozenge If X is defined (from Step 1b), replace references in S according to X [Rn].
 - ii. \blacklozenge If M' does not contain a $\langle module\text{-}subprogram\text{-}part \rangle$, move S to construct the $\langle module\text{-}subprogram\text{-}part \rangle$ of M':

- iii. \blacklozenge If M' contains a $\langle module\text{-subprogram-part} \rangle P$, move S into P.
- (c) For each Reference R to N...
 - i. If R occurs in the context of an $\langle access\text{-}stmt \rangle$ A and A has not been moved into M' by the following step...
 - A. \blacklozenge If every $\langle access-id \rangle$ references a Named Entity in D, move A into the list of $\langle declaration-construct \rangle$ s in M'.
 - B. ♦ Otherwise...

Let S denote the $\langle access-spec \rangle$ of A.

- (1) Remove the $\langle use-name \rangle$ of R and an appropriate adjacent comma.
- (2) Insert a new \(access-stmt \)

$$\langle access\text{-}stmt \rangle \leftarrow S :: R \triangleleft$$

into the list of $\langle declaration\text{-}construct \rangle$ s in M'.

6. \blacklozenge If, after completing Step 5, the $\langle module\text{-}subprogram\text{-}part \rangle$ of M is empty but M still contains a $\langle contains\text{-}stmt \rangle$, remove the $\langle contains\text{-}stmt \rangle$ from M.

Notes.

In a differential refactoring engine, precondition [PP] can be eliminated: When entities are moved from M to M', name bindings to private entities in M will be eliminated (or skewed), resulting in a preservation failure. Precondition [RN] can also be eliminated, since the renamed entities will no longer exist, resulting in a compilation error and/or skewed bindings. Checks [LC] and [SK] can be eliminated from Step 1 as described in their descriptions. Step 1(a)(i) cannot be eliminated since it restricts the number of constructs on which the transformation can operate. The preservation analysis is only applied in Step 5 (after the use statements have been updated): new incoming name binding edges (from the updated use statements) will appear, but, otherwise, name bindings should be preserved. Therefore, this step proceeds according to rule N_{\supseteq}^{\square} .

Part II
BC

5 Definitions

Array Declaration. A declaration of an array variable in a \(\define_list \): LETTER []

Global Variable. A LETTER.

Name. A LETTER.

Scalar Declaration. A declaration of a scalar variable in a \(\langle \textit{define_list} \): LETTER

Variable Declaration. An Array Declaration or a Scalar Declaration.

6 Predicates, Preconditions, & Procedures

6.1 Procedure [Ds]: Compute Dynamic Shadowing for Program *P*

Since BC is dynamically scoped, this procedure uses a simple, interprocedural data flow analysis to determine what local variables may be accessed by other functions.

Input. A $\langle program \rangle P$.

Output. A function *uses*, which maps a $\langle function \rangle$ to a set of Variable Declarations.

Procedure.

- 1. (Compute the call graph for P.) Construct a directed graph whose node set consists of all $\langle function \rangle$ s in P and the whose edges are determined by the **calls** relation defined as follows:
 - (a) For each $\langle function \rangle F$ in P...
 - i. For each $\langle expression \rangle$ in the context of F which has the form G(A) for some LETTER G and $\langle opt_argument_list \rangle A...$
 - A. Define *F* calls *G*.
- 2. (Compute the solution to the reaching definitions problem on the call graph.)

Let *X* denote the set of all Variable Declarations in *P*.

- (a) For each $\langle function \rangle F$ in P...
 - i. Define *gen*(*F*) to be the set of all Variable Declarations in *F*. (Note that this is a subset of *X*.)
 - ii. Define kill(F) to be the set of all Variable Declarations in X which have the same name as a Variable Declaration in F.
 - iii. Initially, let $reaches(F) := \emptyset$.
- (b) For each $\langle function \rangle G$ in P...
 - i. Let *reaches*(*G*) be the least solution to the equation

$$\mathit{reaches}(G) = \bigcup_{F \in \mathbf{calls}^{-1}(G)} (\mathit{gen}(F) \cup (\mathit{reaches}(F) \cap \neg \mathit{kill}(F))) \,.$$

- 3. (Compute du-chains on the call graph.) Define a function uses as follows. For each $\langle function \rangle F$ in P...
 - (a) For each reference in F to a variable V...
 - i. If F does not contain a Variable Declaration for V...
 - A. every Variable Declaration in reaches(F) with the name V is included in uses(F).
 - B. every Global Variable with the name V is included in uses(F).
- 4. Return the function uses.

6.2 Precondition [IN]: Introducing Variable Declaration V into Function F must be legal and name bindingpreserving

This precondition makes two guarantees: (1) if a particular declaration is added to a program, the it will not introduce duplicate local variables, and (2) if the declaration will shadow another declaration, it will not inadvertently change references to the shadowed declaration.

Input. A new Variable Declaration V and a Function F.

Procedure. Compute dynamic shadowing for F [Ds] to obtain the function *uses*.

- 1. Fail if the $\langle opt_auto_define_list \rangle$ in the context of F contains a declaration matching V.
- 2. FAIL if *uses*(*F*) contains a Variable Declaration with the same name as *V* which does not occur in the context of *F*.
- 3. Pass.

6.3 Procedure [Cv]: Classify Local Variables in Statement Sequence S

This procedure is used by Extract Function to determine which local variables need to be passed as parameters to, and/or returned from, the extracted function.

Input. 1. A sequence $S := S_1, S_2, \dots, S_n$ of consecutive $\langle statement \rangle$ s from a $\langle statement_list \rangle$ in the immediate context of a $\langle function \rangle F$.

Output. 1. A set *X* of Variable Declarations.

2. A function *isParam* : $X \rightarrow \{\text{TRUE}, \text{FALSE}\}.$

3. A function *isReturn* : $X \rightarrow \{\text{TRUE}, \text{FALSE}\}.$

Procedure. 1. Initially, define $X := \emptyset$.

2. For each local variable V declared in F...

(a) If V is referenced in $S \dots$

i. Define $X := X \cup \{V\}$.

- ii. If there is a du-chain for V whose definition lies outside S and whose use lies inside S, define isParam(V) := TRUE. Otherwise, define isParam(V) := FALSE.
- iii. If there is a du-chain for V whose definition lies inside S and whose use lies outside S, define isReturn(V) := TRUE. Otherwise, define isReturn(V) := FALSE.
- 3. Return *X*, *isParam*, and *isReturn*.

7 Refactorings

7.1 Add Unreferenced Local Variable Declaration [Prerequisite]

This refactoring adds a declaration for an (unused) local variable.

- **Input.** 1. A Variable Declaration *V*.
 - 2. A Function F in which V will be declared as a local variable.

Preconditions. 1. Introducing *V* into *F* must be legal and name binding-preserving [IN].

Transformation. 1. If F contains an $\langle opt_auto_define_list \rangle L$,

(a) \blacklozenge If L is nonempty, append

list element \leftarrow , V

Requires: [IN] [Ds]

Requires: (none)

Requires: none

to the $\langle define_list \rangle$ of L.

(b) \blacklozenge If L is empty, append

list element $\leftarrow V$

to the empty $\langle define_list \rangle$ of L.

2. \blacklozenge If F does not contain an $\langle opt_auto_define_list \rangle$, insert

$$\langle opt_auto_define_list \rangle \leftarrow auto V$$

to the $\langle define_list \rangle$ of L.

Notes.

In a differential refactoring engine, Precondition [IN] can be eliminated, since, depending on the implementation, a conflict will either result in a compilability error or the introduction of additional (ambiguous) name binding edges, and shadowing will result in skewed name binding edges. The new variable should have no incoming name bindings. Therefore, this refactoring should preserve the program graph in its entirety.

7.2 Replace Statement with Block [Prerequisite]

This refactoring replaces a statement S with a block $\{S\}$.

Input. A $\langle statement \rangle S$.

Preconditions. None.

Transformation. \blacklozenge Replace S with

 $\langle statement \rangle \leftarrow \{S\}$

Notes.

This refactoring is always legal: If S is a $\langle statement \rangle$, $\{S\}$ is also a $\langle statement \rangle$, according to the BC grammar. The BC specification does not contain any extragrammatical restrictions on where particular statements may or may not occur.

7.3 Insert Assignment to Unreferenced Local Variable [Prerequisite]

This refactoring inserts an assignment statement which assigns the value 0 to an otherwise unreferenced local variable.

Input. 1. A Scalar Variable *V* to be assigned.

2. A (statement list) into which an assignment statement will be inserted, and the position at which it should be inserted.

Preconditions. There must be no references to V.

Transformation. ♦ Insert

 $\langle statement \rangle \leftarrow V = 0 \, 4$

at the given position in the given (*statement_list*).

Notes.

The precondition for this refactoring is automatically satisfied when this refactoring is part of the Extract Function refactoring. Nevertheless, it is unnecessarily strong: The purpose of the precondition is to avoid introducing an assignment that would change the behavior of the program, i.e., to avoid introducing a new def-use edge. The assignment statement will have an outgoing name binding edge to the variable declaration, and control flow will not be preserved, but def-use edges should be preserved. Therefore, this refactoring proceeds according to the rule $N \supseteq D$.

7.4 Move Expression Into Assignment [Prerequisite]

Requires: none

This refactoring moves an expression from its original context into an assignment statement and then replaces the original expression with a use of the assigned variable.

Input. 1. An $\langle expression \rangle E$ occurring in the context of a $\langle function \rangle$.

2. An assignment statement A of the form $V = \emptyset$ for a Scalar Variable V.

Preconditions. Let S denote the least $\langle statement \rangle$ containing E.

1. S must exist in the immediate context of a $\langle statement \ list \rangle$. Let L denote this $\langle statement \ list \rangle$.

2. There must be no references to *V* except for the reference in *A*.

3. The assignment statement *A* must exist in the immediate context of *L*.

4. For each $\langle statement \rangle S'$ occurring after A but before S in L...

(a) Fail if S' assigns a Variable occurring in E.

Transformation.

- 1. ♦ In the assignment statement, replace the RHS expression ∅ with E, removing E from its current context.
- 2. \blacklozenge In E's original context, insert

$$\langle expression \rangle \leftarrow V$$

Notes.

Preconditions 2 and 4 can be eliminated in a differential refactoring engine since they are effectively preserving def-use edges. (For that matter, they are unnecessarily strong.) The affected forest should include both of the replaced expressions (in the assignment statement and in the original context). Then, there will be one internal def-use edge introduced (from the new variable to the assignment statement), but otherwise no def-use edges should be introduced. Introducing the reference to the local variable will add one name binding. Therefore, this refactoring should proceed according to the rule $N \subseteq D^{\circ}$.

7.5 Extract Local Variable

Requires: (prerequisites)

Extract Local Variable removes an expression or subexpression from a statement, assigns it to a local variable, and replaces the original expression with a reference to that local variable.

Although the refactoring ensures that du-chains for local variables are preserved, it is the user's responsibility to ensure that the extracted expression is side effect-free or that the program will exhibit the correct behavior if it is not.

- **Input.** 1. An $\langle expression \rangle E$ in a $\langle function \rangle F$.
 - 2. A new Name *N* for the local variable that will be created.

Preconditions. 1

- 1. *E* must have scalar type.
- 2. F must not declare or reference a scalar named N.

Transformation.

- 1. Add an Unreferenced Local Variable Declaration for *N* [Prerequisite]. Let *S* denote the least $\langle statement \rangle$ in which *E* occurs.
- 2. \blacklozenge If S is the \langle statement \rangle providing the body of a for-statement, if-statement, or while-statement, Enclose S in a Block [Prerequisite], and, in the remaining steps, assume that S exists in this new context.

(Note that, by construction, S must now exist in the immediate context of a \langle statement_list \rangle .)

- 3. \blacklozenge Insert an Assignment to the Unreferenced Local Variable N [Prerequisite] immediately before S.
- 4. ♦ Move *E* Into the Assignment statement inserted in the previous step [Prerequisite].

Notes. —

7.6 Add Empty Function

This refactoring adds a new $\langle function \rangle$ to a $\langle program \rangle$. The $\langle function \rangle$ initially has an empty body. The refactoring fails if a $\langle function \rangle$ with the same name already exists.

- Input.
- 1. A $\langle program \rangle P$.
- 2. A new name (LETTER) N for the function.

Preconditions.

Fail if any $\langle input_item \rangle$ in P is a $\langle function \rangle$ whose name (Letter) matches N.

Transformation.

 \blacklozenge Append to P

$$\langle input_item \rangle \leftarrow define N() \{ \neq \} \}$$

Notes.

In a differential refactoring engine, the precondition can be eliminated: Depending on the implementation, introducing a function with the same name as an existing function will either result in a compilability error or the introduction of new def-use or name binding edges. Therefore, this refactoring should preserve the program graph in its entirety.

7.7 Populate Unreferenced Function

Requires: [Cv]

Requires: none

This refactoring copies statements from one function into another, replacing local variables with function arguments and returning the value of a variable if necessary. The refactoring fails if more than one value must be returned.

Input.

1. A sequence $S := S_1, S_2, \dots, S_n$ of consecutive $\langle statement \rangle$ s from a $\langle statement_list \rangle$ in the immediate context of a $\langle function \rangle$.

Preconditions.

- 1. There must not be a return statement in the context of S.
- 2. (Checked during transformation)

Transformation.

- 1. Classify local variables in S [Cv] to obtain the set X and the functions is Param and is Return.
- 2. \diamond Fail if |isReturn(X)| > 1.

- 3. (Construct an $\langle opt_auto_define_list \rangle$ A and an $\langle opt_parameter_list \rangle$ P.)
 - (a) Initially, let *A* and *P* be empty.
 - (b) For each V in X...
 - i. If isParam(V) = TRUE, append V (and a comma, if necessary) to P.
 - ii. If isParam(V) = FALSE...
 - A. If *A* is empty, define *A* to be

```
\langle opt\_auto\_define\_list \rangle \leftarrow auto V
```

- B. Otherwise, append V (and a comma, if necessary) to A's $\langle define\text{-}list \rangle$.
- 4. (Construct a return statement R.)
 - (a) Initially, let *R* be empty.
 - (b) If $isReturn(X) = \{V\}$ for some V...
 - i. Define *R* to be

$$\langle statement \rangle \leftarrow return N(V) \downarrow$$

5. \blacklozenge Replace F with

$$\langle function \rangle \leftarrow \text{define } N(P) \ \{ \emptyset \}$$

$$A \emptyset$$

$$S_1 \emptyset$$

$$S_2 \emptyset$$

$$\dots$$

$$S_n \emptyset$$

$$R \emptyset$$

where A and R are omitted if they are empty.

Notes.

In a differential refactoring engine, both preconditions can be eliminated, as long as this refactoring is being used only in the Extract Function composite: This is because a failure to meet these preconditions will cause Replace Statement Sequence to fail. If the statement sequence includes a RETURN statement, this control flow will be lost when the statement sequence is replaced. Similarly, if more than one value needs to be returned, a def-use chain will be lost when the statement sequence is replaced.

7.8 Replace Statement Sequence S

Requires: [Cv]

This refactoring replaces a sequence of statements with an equivalent function call. This refactoring is not intended to be used except as part of Extract Function.

- **Input.** 1. A sequence $S := S_1, S_2, \dots, S_n$ of consecutive $\langle statement \rangle$ s from a $\langle statement_list \rangle$ in the immediate context of a $\langle function \rangle$.
 - 2. A new Name N.

Preconditions.

(none)

Transformation.

- 1. Classify local variables in S [Cv] to obtain the set X and the functions is Param and is Return.
- 2. (Construct an \(opt_parameter_list \(\) P.)
 - (a) Initially, let *P* be empty.
 - (b) For each V in X...
 - i. If isParam(V) = TRUE, append V (and a comma, if necessary) to P.

3. \blacklozenge If $isReturn(X) = \{V\}$ for some V, replace S with

$$\langle statement_list \rangle \leftarrow V = N(P) \downarrow$$

4. \blacklozenge Otherwise, replace S with

$$\langle statement_list \rangle \leftarrow N(P) \triangleleft$$

Notes.

In a differential refactoring engine, this replacement is expected to preserve incoming and outgoing control flow and du-chains if it is to preserve behavior. Clearly, the set of name bindings will change. Therefore, this refactoring proceeds according to the rule $C \subseteq D \subseteq \mathbb{R}$.

Requires: (prerequisites)

7.9 Extract Function

Extract Function creates a new method from a sequence of statements and replaces the original statements with a call to that method.

Input. 1. A sequence $S := S_1, S_2, \dots, S_n$ of consecutive $\langle statement \rangle$ s from a $\langle statement_list \rangle$ in the immediate context of a $\langle function \rangle$.

2. A new Name N.

Preconditions. (none)

Transformation. 1. \blacklozenge Add an empty function named N [Prerequisite]. Call this function F.

2. \blacklozenge Populate F according to S [Prerequisite].

3. \blacklozenge Replace S with a call to F [Prerequisite].

Notes. —

Part III PHP

8 Definitions

Class Declaration. An \(\(\lambda\) unticked-class-declaration-statement\).

Class Name. The T_STRING in an \(\langle unticked-class-declaration-statement \rangle \).

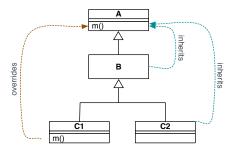

Method Declaration. A (*class-statement*) matching

\(\lambda\) method-modifiers \(\lambda\) function \(\lambda\) is-reference \\\ \tau_\text{STRING}\) (\(\lambda\) parameter-list \(\lambda\)) \(\lambda\) method-body \(\lambda\)

Method Name. The T_STRING in a Method Declaration.

9 Preconditions

9.1 Precondition [II]: Introducing M into Class C' must not introduce unexpected inheritance

In a situation such as the one illustrated above, method m cannot be pulled up from C1 into B because this would cause C2 to inherit the pulled up method. This precondition prevents situations like this, where a class would inherit the "wrong" override of a method.

Input. A Method Declaration M in a Class Declaration C with a direct superclass C'.

Procedure.

- 1. If *M* does not override a concrete superclass method, PASS.

 Otherwise, suppose *M* overrides *M'*, which is defined in class *P*.
- 2. For each (direct or indirect) subclass D of P...
 - (a) Fail if all of the following hold:
 - i. D inherits M' from P.
 - ii. D is a (direct or indirect) subclass of C'.
 - iii. $D \neq C$.
- 3. Pass.

10 Refactorings

10.1 Copy Up Method [Prerequisite]

Copy Up Method copies a method from one class into its immediate superclass.

Input. A Method Declaration *M* in the context of a Class Declaration *C*.

Preconditions.

1. There must be an $\langle extends-from \rangle$ node in the immediate context of C, and its $\langle fully-qualified-class-name \rangle$ must (uniquely) identify a Class Declaration C' in the same file as C.

Requires: [II]

Requires: (prerequisites)

- 2. *M*'s (*method-modifiers*) must not contain T_ABSTRACT OF T_STATIC.
- 3. C' must not contain a Method Declaration with the same name as M.
- 4. If there are any references to *M* that are not recursive references contained in *M*, then *M* must not have private visibility.
- 5. *M* must not contain any references to self or __CLASS__.
- 6. *M* must not contain any references to private members of *C*.
- 7. Moving M to C' must not introduce unexpected inheritance [II].
- 8. If M overrides a concrete method, and C' is not an abstract class, warn the user that M will replace the overridden method in C', possibly changing the behavior of objects of that type.
- 9. If C' defines or inherits __call, and M does not override a superclass method, warn the user: the program's behavior may change, since M will be invoked instead of __call for objects of type C'.

Transformation.

♦ Move the $\langle class\text{-}statement \rangle$ containing M from C's $\langle class\text{-}statement\text{-}list \rangle$ into C''s $\langle class\text{-}statement\text{-}list \rangle$, replacing all references to parent with self.

Notes.

We require the superclass to be in the same file as C in order to avoid dealing with include directives.

In a differential refactoring engine, precondition 3 will be caught by a compilability check. Preconditions 4–6 are simply preserving name bindings. A program that failed precondition 7 would introduce an incoming inheritance edge. If a program failed precondition 8, an outgoing inheritance edge from C' would vanish. Preconditions 1 and 2 cannot be eliminated because they perform input validation; precondition 9 checks for behavior that is not modeled by a program graph. This refactoring proceeds with preservation rule $NO_{\geq}^{\circ}I$.

10.2 Pull Up Method

Pull Up Method moves a method from one class into its immediate superclass.

Input. A Method Declaration *M* in the context of a Class Declaration *C*.

Preconditions. None.

Transformation. 1. ♦

1. ♦ Copy Up *M* [Prerequisite].

2. \blacklozenge Delete the $\langle class\text{-statement} \rangle$ containing M from C's $\langle class\text{-statement-list} \rangle$

Notes. All of the preconditions for this refactoring are handled by Copy Up Method. The delete operation proceeds with preservation rule $NO \subseteq I \subseteq I$.
